

where μ is the mean of the response variable, η is the linear predictor, and σ^2 is the variance of the response variable. The linear predictor is a linear combination of the explanatory variables, and the variance is a function of the linear predictor. The GLM framework is a generalization of the linear model, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model.

10.1 The GLM framework and its components

The GLM framework is a generalization of the linear model, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model. The GLM framework is a generalization of the linear model, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model. The GLM framework is a generalization of the linear model, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model.

The GLM framework is a generalization of the linear model, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model.

The GLM framework is a generalization of the linear model, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model. The GLM framework is a generalization of the linear model, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model. The GLM framework is a generalization of the linear model, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model.

The GLM framework is a generalization of the linear model, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model. The GLM framework is a generalization of the linear model, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model.

10.1.1 The linear model

The linear model is a special case of the GLM framework, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model. The linear model is a special case of the GLM framework, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model. The linear model is a special case of the GLM framework, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model.

The linear model is a special case of the GLM framework, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model. The linear model is a special case of the GLM framework, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model. The linear model is a special case of the GLM framework, and it includes a wide range of models, including the linear model, the logistic model, and the Poisson model.

10.2 Statistical inference and model diagnostics

10.2.1 Statistical inference

Statistical inference is a branch of statistics that deals with the process of making inferences about a population based on a sample. It includes a wide range of methods, including hypothesis testing, confidence intervals, and Bayesian inference.
